

# Human Gene Therapy for Rare Diseases

---

## Draft Guidance for Industry

**This guidance document is for comment purposes only.**

Submit one set of either electronic or written comments on this draft guidance by the date provided in the *Federal Register* notice announcing the availability of the draft guidance. Submit electronic comments to <https://www.regulations.gov>. Submit written comments to the Dockets Management (HFA-305), Food and Drug Administration, 5630 Fishers Lane, Rm. 1061, Rockville, MD 20852. You should identify all comments with the docket number listed in the notice of availability that publishes in the *Federal Register*.

Additional copies of this guidance are available from the Office of Communication, Outreach and Development (OCOD), 10903 New Hampshire Ave., Bldg. 71, Rm. 3128, Silver Spring, MD 20993-0002, or by calling 1-800-835-4709 or 240-402-8010, or email [ocod@fda.hhs.gov](mailto:ocod@fda.hhs.gov), or from the Internet at <https://www.fda.gov/BiologicsBloodVaccines/GuidanceComplianceRegulatoryInformation/Guidances/default.htm>.

For questions on the content of this guidance, contact OCOD at the phone numbers or email address listed above.

**Human Gene Therapy for Rare Diseases**

---

**Draft Guidance for Industry**

*This draft guidance, when finalized, will represent the current thinking of the Food and Drug Administration (FDA or Agency) on this topic. It does not establish any rights for any person and is not binding on FDA or the public. You can use an alternative approach if it satisfies the requirements of the applicable statutes and regulations. To discuss an alternative approach, contact the FDA staff responsible for this guidance as listed on the title page.*

**I. INTRODUCTION**

This guidance provides recommendations to stakeholders developing a human gene therapy (GT) product<sup>1</sup> intended to treat a rare disease<sup>2</sup> in adult and/or pediatric patients regarding the manufacturing, preclinical, and clinical trial design issues for all phases of the clinical development program. Such information is intended to assist sponsors in designing clinical development programs for such products, where there may be limited study population size and potential feasibility and safety issues, as well as issues relating to the interpretability of bioactivity/efficacy outcomes that may be unique to rare diseases or to the nature of the GT product itself.

FDA’s guidance documents, including this guidance, do not establish legally enforceable responsibilities. Instead, guidances describe the FDA’s current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements are cited. The use of the word *should* in FDA’s guidances means that something is suggested or recommended, but not required.

---

<sup>1</sup> Human gene therapy seeks to modify or manipulate the expression of a gene or to alter the biological properties of living cells for therapeutic use. Human gene therapy products are defined as all products that mediate their effects by transcription or translation of transferred genetic material or by specifically altering host (human) genetic sequences. Some examples of gene therapy products include nucleic acids, genetically modified microorganisms (e.g., viruses, bacteria, fungi), engineered site-specific nucleases used for human genome editing (Ref. 1), and ex vivo genetically modified human cells. Gene therapy products meet the definition of “biological product” in section 351(i) of the Public Health Service (PHS) Act (42 U.S.C. 262(i)) when such products are applicable to the prevention, treatment, or cure of a disease or condition of human beings.

<sup>2</sup> A rare disease is defined by the Orphan Drug Act of 1983 as a disorder or condition that affects fewer than 200,000 persons in the United States. Public Law 97-414, 96 Stat. 2049 (1983). Amended by Public Law 98-551 (1984) to add a numeric prevalence threshold to the definition of rare diseases.

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

### 31 **II. BACKGROUND**

32  
33 The National Institutes of Health (NIH) reports that nearly 7,000 rare diseases affect more than  
34 25 million Americans. Approximately 80% of rare diseases are caused by a single-gene defect,  
35 and about half of all rare diseases affect children. Since most rare diseases have no approved  
36 therapies, there is a significant unmet need for effective treatments, and many rare diseases are  
37 serious or life-threatening conditions. As a general matter, developing safe and effective  
38 products to treat rare diseases can be challenging. For example, it might be more difficult to find  
39 and recruit patients with rare diseases into clinical trials. Additionally, many rare diseases  
40 exhibit a number of variations or sub-types. Consequently, patients may have highly diverse  
41 clinical manifestations and rates of disease progression with unpredictable clinical courses.  
42 These challenges are also present for the development of GT products. However, despite these  
43 challenges, GT-related research and development in the area of rare diseases continues to grow  
44 at a rapid rate.

### 45 46 47 **III. CONSIDERATIONS FOR PRODUCT DEVELOPMENT**

48  
49 The general chemistry, manufacturing and control (CMC) considerations for product  
50 manufacturing, testing and release of GT products for rare diseases are the same as those  
51 described for other GT products (Ref. 2). However, some aspects of the development programs  
52 for rare diseases, such as limited population size and fewer lots manufactured, may make it  
53 challenging to follow traditional product development strategies. In traditional product  
54 development, critical quality attributes (CQA) of the product are evaluated during each phase of  
55 clinical development, and characterization data from many product lots are correlated to clinical  
56 outcomes. In addition, GT products may have CQA with higher variability than drugs or well-  
57 characterized biologics, which can add to CQA uncertainty. Smaller study populations may  
58 result in the need for fewer manufacturing runs, which can make it difficult to establish the  
59 critical process parameters (CPP) necessary for ensuring CQA. However, demonstrating process  
60 control to ensure a consistent product with predefined CQA for potency, identity and purity is  
61 required to demonstrate compliance with licensure and regulatory requirements.<sup>3</sup>

62  
63 These factors make it even more critical that a sponsor of a GT product for a rare disease  
64 establish a well-controlled manufacturing process along with suitable analytical assays to assess  
65 product CQA as early in development as possible, optimally before administration of the GT  
66 product to the first subject. Importantly, as the phase 1 study may provide evidence of safety and  
67 effectiveness, characterization of product CQA and manufacturing CPP should be implemented  
68 during early clinical development, and innovative strategies such as the production of multiple  
69 small lots versus a single large product lot may be considered. Sponsors developing GT products  
70 for rare diseases are strongly encouraged to contact the Office of Tissues and Advanced  
71

---

<sup>3</sup> Section 351(a)(2)(C)(i) of the PHS Act (42 U.S.C. 262(a)(2)(C)(i)); 21 CFR 601.2; 21 CFR 601.20; 21 CFR Part 610, Subpart B.

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

72 Therapies (OTAT) in the Center for Biologics Evaluation and Research (CBER) prior to  
73 investigational new drug application (IND) submission to discuss their product-specific  
74 considerations, which may include:  
75

- 76 • Product-related variations, including those contributed by intrinsic differences among  
77 subjects' cells, may have a more pronounced effect on the interpretability of smaller rare  
78 disease studies. This is equally true of impurities such as empty and wild type viral  
79 particles that may be present in viral vectors. Establishment of assays for  
80 characterization of product-related variants and impurities will be important for program  
81 success.  
82
- 83 • Potency assays are critical to assess product functional activity, consistency, stability, and  
84 to provide evidence of comparability after changes to the manufacturing process.  
85 Therefore, we strongly encourage the evaluation of multiple product characteristics that  
86 could be used to establish a potency test during initial clinical studies. As these assays  
87 are critical to product development, we recommend that a potency test that measures a  
88 relevant biological activity be qualified for suitability (i.e., accurate, precise, sensitive,  
89 specific) prior to conducting trials intended to provide substantial evidence of  
90 effectiveness for a marketing application, and validated for licensure (Ref. 3).  
91
- 92 • Limited availability of starting materials (e.g., autologous cells) and reference materials  
93 to design suitable assays to measure CQA, as well as limited process understanding, can  
94 hamper manufacturing process development, comparability studies, and process  
95 validation (Ref. 4). Sponsors are encouraged to consider, where possible, implementing  
96 manufacturing changes needed for commercial-scale production and demonstrating  
97 product comparability prior to the initiation of clinical trials intended to provide  
98 substantial evidence of effectiveness for a marketing application. Importantly, if product  
99 comparability cannot be demonstrated, additional clinical studies may be needed.  
100

#### 101 102 **IV. CONSIDERATIONS FOR PRECLINICAL STUDIES**

103  
104 A preclinical program that is tailored to the investigational product and planned early-phase  
105 clinical trial contributes to characterization of the product's benefit/risk profile for the intended  
106 patient population. The overall objectives of a preclinical program for a GT product include: 1)  
107 identification of a biologically active dose range; 2) recommendations for an initial clinical dose  
108 level, dose-escalation schedule, and dosing regimen; 3) establishment of feasibility and  
109 reasonable safety of the proposed clinical route of administration (ROA); 4) support of patient  
110 eligibility criteria; and, 5) identification of potential toxicities and physiologic parameters that  
111 help guide clinical monitoring for a particular investigational product. In addition, to justify  
112 conducting a first-in-human clinical trial in pediatric subjects that is associated with more than a  
113 minor increase over minimal risk, the preclinical program should include studies designed to  
114

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

115 demonstrate a prospect of direct benefit (21 CFR 50.53) of the investigational GT product (refer  
116 to section V.A. of this document for further discussion). This objective is important when  
117 clinical evidence is not available from adult subjects with the same disease.  
118

119 Further details for general considerations in preclinical studies are available in a separate  
120 guidance document (Ref. 5). Although not specific to rare diseases, the following elements are  
121 recommended in the development of a preclinical program for an investigational GT product:  
122

- 123 • Preclinical *in vitro* and *in vivo* proof-of-concept (POC) studies are recommended to  
124 establish feasibility and support the scientific rationale for administration of the  
125 investigational GT product in a clinical trial. Data derived from preclinical POC studies  
126 can guide the design of both the preclinical toxicology studies, as well as the early-phase  
127 clinical trials. The animal species and/or models selected should demonstrate a  
128 biological response to the investigational GT product that is similar to the expected  
129 response in humans.  
130
- 131 • Biodistribution studies should be conducted to assess the pharmacokinetic (PK) profile of a  
132 GT product (Ref. 6). These data encompass the distribution profile of the vector from  
133 the site of administration to target and non-target tissues, including biofluids (e.g., blood,  
134 lymph node fluid, cerebrospinal fluid (CSF)) as applicable. These data can determine  
135 extent of tissue transduction and transgene expression, evaluate whether expression is  
136 transient or persistent, and guide the design of the preclinical toxicology studies as well  
137 as the early-phase clinical trials.  
138
- 139 • Toxicology studies for an investigational GT product should incorporate the elements of  
140 the planned clinical trial (e.g., dose range, ROA, dosing schedule, evaluation endpoints,  
141 etc.) to the extent feasible. Study designs should be sufficiently comprehensive to permit  
142 identification, characterization, and quantification of potential local and systemic  
143 toxicities, their onset (i.e., acute or delayed) and potential mitigation and resolution, and  
144 the effect of dose level on these findings. In some cases, additional assessments may also  
145 be important to consider, such as safety and feasibility of the proposed GT delivery  
146 system and procedure, and immune response directed against vector and expressed  
147 transgene product.  
148
- 149 • The conduct of additional nonclinical studies<sup>4</sup> may be needed to address such factors as:  
150 1) the potential for developmental and reproductive toxicity; and 2) significant changes in  
151 the manufacturing process or formulation that may impact comparability between the  
152 product administered in clinical trials and the product intended for licensure.

---

<sup>4</sup> The preclinical program for any investigational product should be individualized with respect to scope, complexity, and overall design, to maximize the contribution and predictive value of the resulting data for clinical safety and therapeutic activity. We encourage sponsors to explore opportunities for reducing, refining, and replacing animal use in the preclinical program. For example, it may be appropriate to use *in vitro* or *in silico* testing to complement or replace animal studies. Sponsors are encouraged to submit proposals and justify any potential alternative approaches, which we will evaluate for equivalency to animal studies.

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

### 153 **V. CONSIDERATIONS FOR CLINICAL TRIALS**

154  
155 Many rare disorders are serious, with no approved treatments and represent substantial unmet  
156 medical needs for patients. Because of phenotypic heterogeneity, disease manifestations are  
157 likely to vary in onset and severity. Information obtained from a natural history study can  
158 potentially provide critical information to guide every stage of drug development from drug  
159 discovery to determining effectiveness and safety of the drug in treating a disease (Ref. 7).  
160 However, there may be insufficient information on the natural history of the disease to inform  
161 the selection of a historical comparator or to inform clinical endpoint selection in future clinical  
162 trials.

163  
164 In a majority of these disorders, clinical manifestations appear early in life, and there are ethical  
165 and regulatory considerations regarding enrollment of children in clinical trials. These  
166 considerations should factor into the design of both early- and late-phase clinical trials. Further  
167 details of general considerations for GT clinical trials are available in a separate guidance  
168 document (Ref. 8).

169  
170 The following important elements are recommended for consideration during clinical  
171 development of investigational GT products intended for treatment of rare diseases (although  
172 they are not exclusively applicable to GT products for rare diseases).

#### 173 174 **A. Study Population**

175  
176 Selection of the study population should consider existing preclinical or clinical data to  
177 determine the potential risks and benefits for the study subjects. In addition, sponsors  
178 should consider whether the proposed study population is likely to provide informative  
179 safety and/or efficacy data (Ref. 8). The following points should be considered with  
180 respect to trials of GT products for rare diseases:

- 181
- 182 • If the disease is caused by a genetic defect, the sponsor should perform genetic  
183 test(s) for the specific defect(s) of interest in all clinical trial subjects. This  
184 information is important to ensure correct diagnosis of the disorder of interest. In  
185 addition, since many of these disorders can involve either deletions or functional  
186 mutations at any of several loci within a specific gene, safety and effectiveness  
187 may be linked to genotype in unpredictable ways. Given this, early understanding  
188 of such associations may help in planning future clinical trials. Therefore, if there  
189 are no readily available, reliable means of obtaining the needed genetic diagnosis,  
190 a companion diagnostic may be needed and therefore should be considered early  
191 in development.
  - 192 • Pre-existing antibody to the GT product may limit its therapeutic potential.  
193 Sponsors may choose to exclude patients with pre-existing antibodies to the GT  
194 product. In such cases, the sponsor should strongly consider contemporaneous  
195 development of a companion diagnostic to detect antibodies to the GT product. If  
196 an *in vitro* companion diagnostic is needed to appropriately select patients for  
197

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

198 study (and later, once the GT product is approved, for treatment), then submission  
199 of the marketing application for the companion diagnostic and submission of the  
200 biologics license application for the GT product should be coordinated to support  
201 contemporaneous marketing authorizations.  
202

- 203 • Severity of disease should be considered in designing clinical GT trials (Ref. 8),  
204 as well as the anticipated risk and potential benefits to subjects. Subjects with  
205 severe or advanced disease might experience confounding adverse events that are  
206 related to the underlying disease rather than to the GT product itself; however,  
207 they may be more willing to accept the risk of an investigational GT product in  
208 the context of the anticipated clinical benefit.  
209
- 210 • Since most rare diseases are pediatric diseases or have onset of manifestations in  
211 childhood, pediatric studies are a critical part of drug development. However,  
212 treatment in pediatric patients cannot proceed without addressing ethical  
213 considerations for conducting investigations in vulnerable populations. Unless  
214 the risks of an investigational drug are no more than a minor increase over  
215 minimal risk (21 CFR 50.53), the administration of an investigational drug in  
216 children must offer a prospect of direct clinical benefit to individually enrolled  
217 patients, the risk must be justified by the anticipated benefit, and the anticipated  
218 risk-benefit profile must be at least as favorable as that presented by accepted  
219 alternative treatments (21 CFR 50.52). Additionally, adequate provisions must be  
220 made to obtain the permission of the parents and the assent of the child as per 21  
221 CFR 50.55.  
222
- 223 • The risks of most GT products include the possibility of unintended effects that  
224 may be permanent, along with adverse effects due to invasive procedures that  
225 may be necessary for product administration. Because of these risks, it is  
226 generally not acceptable to enroll normal, healthy volunteers into GT studies. A  
227 well-written informed consent document is also essential.  
228

### **B. Study Design**

229  
230  
231 For rare diseases, there may be a limited number of patients who may qualify for  
232 enrollment into a clinical study. As a result, it is often not feasible to enroll unique  
233 subjects for all studies conducted under different phases of the clinical development  
234 program. Limitation in the number of prospective subjects warrants the collection of as  
235 much pertinent data (e.g., adverse events, efficacy outcomes, biomarkers) as possible  
236 from every subject, starting from the first-in-human study. All such data may be valuable  
237

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

238 to inform the design of subsequent studies (e.g., selection of study populations and  
239 endpoints). Sponsors developing GT products for rare diseases should consider the  
240 following:

- 241
- 242 • The randomized, concurrent-controlled trial is generally considered the ideal  
243 standard for establishing effectiveness and providing treatment-related safety  
244 data. Randomization in early stages of development is strongly encouraged when  
245 feasible.
- 246
- 247 • Sponsors should consider designing their first-in-human study to be an adequate  
248 and well-controlled investigation that has the potential, depending on the study  
249 results, to provide evidence of effectiveness to support a marketing application.
- 250
- 251 • To promote interpretability of data for studies that enroll subjects with different  
252 disease stages or severities, sponsors should consider stratified randomization  
253 based on disease stage/severity.
- 254
- 255 • For some GT indications (e.g., a genetic skin disease), the use of an intra-subject  
256 control design may be useful. Comparisons of local therapeutic effects can be  
257 facilitated by the elimination of variability among subjects in inter-subject  
258 designs.
- 259
- 260 • A single-arm trial using historical controls, sometimes including an initial  
261 observation period, may be considered if there are feasibility issues with  
262 conducting a randomized, controlled trial.
- 263
- 264 • If use of a type of single-arm trial design with a historical control is necessary,  
265 then knowledge of the natural history of disease is critical. Natural history data  
266 may provide the basis of a historical control, but only if the control and treatment  
267 populations are adequately matched, in terms of demographics, concurrent  
268 treatment, disease state, and other relevant factors. In circumstances where  
269 randomized, concurrent controlled trials cannot be conducted and the natural  
270 history is well characterized, sponsors may consider the clinical performance of  
271 available therapies (if there are any) when setting the performance goal or criteria  
272 against which the product effect will be tested.
- 273
- 274 • A small sample size, together with high inter-subject variability in clinical course,  
275 diminishes a study's power to detect treatment-related effects. Therefore,  
276 alternative trial designs and statistical techniques that maximize data from a small  
277 and potentially heterogeneous group of subjects should be considered. Ideally,  
278 utilizing as an endpoint a treatment outcome that virtually never occurs in the  
279 natural course of the disease would greatly facilitate the design and cogency of  
280 small trials.
- 281

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

- 282
- Adequate measures to minimize bias should be undertaken. The preferred approach to minimize bias is to use a study design that includes blinding.
- 283
- 284

### C. Dose Selection

285

286

- Dose selection should be informed by all available sources of clinical information (e.g., publications, experience with similar products, experience in related patient populations).
  - Leveraging non-human data obtained in animal models of disease and in vitro data may be, in some cases, the only way to estimate a starting human dose that is anticipated to provide benefit. Additional dosing information can be obtained from predictive models based on current understanding of in vitro enzyme kinetics (including characterizing the enzyme kinetics in relevant cell lines), and allometric scaling.
  - For early-phase studies, clinical development of GT products should include evaluation of two or more dose levels to help identify the potentially therapeutic dose(s). Ideally, placebo controls should be added to each dose cohort.
  - Some GT products may have an extended duration of activity, so that repeated dosing may not be an acceptable risk until there is a preliminary understanding of the product's toxicity and duration of activity.
- 287
- 288
- 289
- 290
- 291
- 292
- 293
- 294
- 295
- 296
- 297
- 298
- 299
- 300
- 301
- 302
- 303
- 304
- 305

Efforts should be made early in the GT product development program to identify and validate biomarkers and to leverage all available information from published investigations for the disease of interest (or related diseases). Some biomarkers or endpoints are very closely linked to the underlying pathophysiology of the disease (e.g., a missing metabolite in a critical biosynthetic pathway). In this case, total or substantial restoration of the biosynthetic metabolic pathway may generally be expected to confer clinical benefit. Changes in such biomarkers could be used during drug development for dose-selection, or even as an early demonstration of drug activity.

306

307

308

309

310

311

312

313

314

### D. Safety Considerations

315

316

- Clinical trials should include a monitoring plan that is adequate to protect the safety of clinical trial subjects. The elements and procedures of the monitoring plan should be based upon what is known about the GT product, including preclinical toxicology, as well as CMC information, and, if available, previous human experience with the proposed product or related products (Ref. 8).
  - Innate and adaptive immune responses directed against one or more components of GT products (e.g., against the vector and/or transgene) may impact product safety and efficacy. Early development of appropriate assays to measure product-
- 317
- 318
- 319
- 320
- 321
- 322
- 323
- 324
- 325
- 326

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

327 directed immune responses may be critical to program success. Development of  
328 neutralizing and non-neutralizing immune responses that are directed against the  
329 product should be monitored throughout the clinical trial (Ref. 9).  
330

- 331 • When there is limited previous human experience with a specific GT product,  
332 administration to several subjects concurrently may expose those subjects to  
333 unacceptable risk. Most first-in-human trials of GT products should stagger  
334 administration to consecutively enrolled subjects, for at least an initial group of  
335 subjects, followed by staggering between dose cohorts. This approach limits the  
336 number of subjects who might be exposed to an unanticipated safety risk (Ref. 8).  
337 The optimal dosing interval between consecutively enrolled subjects and dose  
338 cohorts should be discussed with OTAT prior to conduct of the trial.  
339
- 340 • Because of the unique nature of the mechanism of action involving genetic  
341 manipulation, a potential exists for serious long-term effects that may not be  
342 apparent during development or even at the time of an initial licensure. The long-  
343 term safety of GT products is currently unknown. The appropriate duration of  
344 long term follow-up depends on the results of preclinical studies with this  
345 product, knowledge of the disease process, and other scientific information (Ref.  
346 6).  
347
- 348 • Early-phase GT clinical trial protocols should generally include study stopping  
349 rules, which are criteria for halting the study based on the observed incidence of  
350 particular adverse events. The objective of study stopping rules is to limit subject  
351 exposure to risk in the event that safety concerns arise. Well-designed stopping  
352 rules may allow sponsors to assess and address risks identified as the trial  
353 proceeds, and to amend the protocol to mitigate such risks or to assure that human  
354 subjects are not exposed to unreasonable and significant risk of illness or injury.  
355
- 356 • The potential for viral shedding should be addressed early in product development  
357 (Ref. 10).  
358

### **E. Efficacy Endpoints**

359 Demonstration of clinical benefit of a GT product follows the same principles as for any  
360 other product. However, in some cases there may be unique characteristics of GT  
361 products (e.g., a protein that is expressed by a GT product may have different bioactivity  
362 than standard enzyme replacement therapy) that warrant additional considerations both  
363 pre-approval and post-marketing. Prior to commencing clinical trials of GT products for  
364 rare diseases, it is critically important to have a discussion with FDA about the primary  
365 efficacy endpoint(s). For many rare diseases, well-established, disease-specific efficacy  
366 endpoints are not available (Ref. 11). Endpoint selection for a clinical trial of a GT  
367 product for a rare disease should consider the following:  
368  
369  
370

- Sponsors should utilize an understanding the pathophysiology and natural history of a disease as fully as possible at the outset of product development. Full understanding of mechanism of product action is not required for product approval; however, understanding of pathophysiology is important in planning clinical trials, including selection of endpoints.
  - For sponsors that are considering seeking accelerated approval of a GT product for a rare disease pursuant to section 506(c) of the Federal Food, Drug, and Cosmetic Act (FD&C Act) based on a surrogate endpoint, it will be particularly important to understand the pathophysiology and natural history of the disease in order to help identify potential surrogate endpoints that are reasonably likely to predict clinical benefit.
  - Sponsors should identify specific aspects of the disease that are meaningful to the patient and might also be affected by the GT product’s activity (Ref. 12).
  - Considerable information can be gained by collecting clinical measurements repeatedly over time. Such longitudinal profile allows the assessments of effect, largely based on within-patient changes, that otherwise could not be studied.

### **F. Patient Experience**

391

392

393

394

395

396

397

Patient experience data<sup>5</sup> may provide important additional information about the clinical benefit of a GT product. FDA encourages sponsors to collect patient experience data during product development, and to submit such data in the marketing application.

## **VI. EXPEDITED PROGRAMS**

400

401

402

403

404

405

There are several programs that may be available to sponsors of GTs intended to address unmet medical needs in the treatment of serious or life-threatening conditions that are intended to facilitate and expedite development and review of these therapies, including regenerative medicine advanced therapy designation, breakthrough therapy designation, fast track designation, accelerated approval, and priority review. In particular, regenerative medicine advanced therapy designation and breakthrough therapy designation call for earlier attention

---

<sup>5</sup> As defined in section 569(c) of the FD&C Act, the term “patient experience data” includes data that are:

- Collected by any persons (including patients, family members and caregivers of patients, patient advocacy organizations, disease research foundations, researchers, and drug manufacturers); and
- Intended to provide information about patients’ experiences with a disease or condition, including the impact (including physical and psychosocial impacts) of such disease or condition, or a related therapy or clinical investigation, on patients’ lives; and patient preferences with respect to treatment of such disease or condition.

Additional information on Patient-Focused Drug Development can be found on this website:

## Contains Nonbinding Recommendations

*Draft – Not for Implementation*

406 from FDA to these potentially promising therapies, offering sponsors earlier and more frequent  
407 interactions with FDA on efficient trial design and overall drug development. Further  
408 information on these programs is available in separate guidance documents<sup>6,7</sup>.

409

410

### 411 **VII. COMMUNICATION WITH FDA**

412

413 FDA recommends communication with OTAT early in product development, before submission  
414 of an IND. There are different meeting types that can be used for such discussions, depending  
415 on the stage of product development and the issues to be considered. These include pre-IND  
416 meetings and, earlier in development, INitial Targeted Engagement for Regulatory Advice on  
417 CBER products (INTERACT) meetings.<sup>8</sup> Early nonbinding, regulatory advice can be obtained  
418 from OTAT through an INTERACT meeting, which can be used to discuss issues such as a  
419 product's early preclinical program, and/or through a pre-IND meeting prior to submission of the  
420 IND (Ref. 13).
